

Getting Spark, Python, and **Jupyter** Notebook running on **Amazon EC2** Step-by-step guide to getting PySpark working with Jupyter Notebook on an instance of

Jose Marcial Portilla Sep 25, 2016 · 5 min read

Hi! I'm Jose Portilla and I teach over 200,000 students about programming,

courses <u>here</u>.

Amazon EC2.

If you're interested in learning Python for Data Science and Machine learning, check out my course here. (I also teach Full Stack Web Development with Django!)

data science, and machine learning on Udemy! You can check out all my

Step 1: Create an Amazon EC2 Instance

of instructions located here. Follow those to the point where you have the connection to the Ubuntu console.

Step 2: SSH into that instance (Windows)

instances or larger instances.

\$ chmod 400 MyKey.pem

Step 3: SSH into that instance (Linux/Mac OS) An SSH client is already built into Mac and Linux (usually). You can just do a straightforward ssh command into your EC2 instance using your .pem file that you downloaded. Amazon also has instructions on this here.

\$ ssh -i MyKey.pem ubuntu@ec2-18-216-190-232.us-east-2.compute.amazonaws.com

virtual Ubuntu instance running on EC2. The rest of the guide will tell you commands to put into this terminal. Step 4: Download and Install Anaconda

replace the version numbers here with whatever version you prefer (2 or 3).

Next we will download and install Anaconda for our Python. You can

\$ wget http://repo.continuum.io/archive/Anaconda3-4.1.1-Linuxx86_64.sh

\$ bash Anaconda3-4.1.1-Linux-x86_64.sh

Enter again to accept the default location.

\$ which python

Or you can just type **python** and check to see.

\$ jupyter notebook --generate-config

them out with some general information.

Step 8: Edit Configuration File

earlier. Change directory to:

type:

使用这个!!!

Configuration file for jupyter-notebook.

Don't open browser by default

c.NotebookApp.port = 8888

Fix port to 8888

console type:

\$ jupyter notebook

Step 10: Install Java

\$ sudo apt-get update

Then install Java with:

Check that it worked with:

\$ java -version

\$ scala -version

Step 12: Install py4j

\$ conda install pip

Now we can install py4j with pip:

Step 13: Install Spark and Hadoop

Step 14: Tell Python where to find Spark

\$ export PATH=\$SPARK_HOME:\$PATH

Step 15: Launch Jupyter Notebook

Spark! Run:

\$ jupyter notebook

If that works, you're all done!

Data Scientist and Online Instructor

Beginners Guide to

PySpark

\$ pip install py4j

\$ which pip

Confirm that the correct pip is being used with:

replace the version numbers):

\$ sudo dpkg -i scala-2.11.8.deb

 $c.NotebookApp.open_browser = False$

Step 7: Create Certifications

files. Perform the following:

\$ mkdir certs

\$ cd certs

Step 5: Check which Python you are using.

Press Enter through the license agreements, then Enter yes to accept, then

Top highlight

\$ source /home/ubuntu/anaconda3/bin/activate \$ source .bashrc \$ conda init Then confirm with:

更高的anaconda可能需要这样做

Step 6: Configure Jupyter Notebook Jupyter comes with Anaconda, but we will need to configure it in order to use it through EC2 and connect with SSH. Go ahead and generate a

\$ sudo openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout mycert.pem -out mycert.pem \$ sudo chmod 777 mycert.pem

You'll get asked some general questions after running that last line. Just fill

\$ vi jupyter_notebook_config.py You should see a bunch of commented Python code, this is where you can either uncomment lines or add in your own (things such as adding

password protection are an option here). We will keep things simple.

Press i on your keyboard to activate -INSERT-. Then at the top of the file

listen on all IPs c.NotebookApp.ip = '0.0.0.0'# Allow all origins c.NotebookApp.allow_origin = '*'

Once you've typed/pasted this code in your config file, press Esc to stop

Step 9: Check that Jupyter Notebook is working

inserting. Then type a colon: and then type wq to write and quit the editor.

Now you can check to see that jupyter notebook is working. In your ubuntu

followed by :8888. It should be in the form: https://ec2-xx-xxx-xxx.us-west-2.compute.amazonaws.com:8888 After putting that into your browser you'll probably get a warning of an untrusted certificate, go ahead and click through that and connect anyway, you trust the site. (Hopefully, after all you are the one that made it!)

You should be able to see Jupyter Notebook running on you EC2 instance.

Great! Now we need to go back and install Scala, Java, Hadoop, and Spark

on that same instance to get PySpark working correctly. Use Crtl-C in your

EC2 Ubuntu console to kill the Jupyter Notebook process. Clear the console

Next we need to install Java in order to install Scala, which we need for

with **clear** and move on to the next steps to install Spark.

Spark. Back at your EC2 command line type:

\$ sudo apt-get install default-jre

You'll see an output saying that a jupyter notebook is running at all ip

addresses at port 8888. Go to your own web browser (Google Chrome

suggested) and type in your Public DNS for your Amazon EC2 instance

Step 11: Install Scala Now we can install Scala: \$ sudo apt-get install scala

Then use conda to install pip:

bin-hadoop2.7.tgz

Use the following to download and install Spark and Hadoop:

Finally we need to set our Paths for Spark so Python can find it:

\$ export SPARK_HOME='/home/ubuntu/spark-2.0.0-bin-hadoop2.7'

You should now have everything set up to launch Juptyer notebook with

\$ export PYTHONPATH=\$SPARK_HOME/python:\$PYTHONPATH

from pyspark import SparkContext sc = SparkContext()

Then as previously done, connect through your browser again to your

instance's Jupyter Notebook. Launch a new notebook and in a notebook cell

O Medium About Help

This is mainly a guide for myself to reference again at a later date, but I figured it would be useful to others. There are a few guides similar to this one floating around, but a lot of them have not been updated in a while. This guide assumes some basic familiarity with the command line and AWS console.

For simplicity we will use the Free Tier Micro Instance using Ubuntu 64x.

editing the Security of the instance. This guide can be expanded to multiple

For Windows users, you'll need to use <u>PuTTY</u>. Amazon has a really good set

Use all the default settings, except set All Traffic instead of SSH when

You should now have successfully connected to the command line of your

Ubuntu already comes with Python, but let's make sure we are using the Anaconda version. Use: \$ which python

Most likely you won't be using Anaconda's version of Python (you can tell

by checking the output of the which python command). Change to the

Anaconda version of Python by specifying your source using:

configuration file for Jupyter using:

We can also create certifications for our connections in the form of .pem

\$ cd ~/.jupyter/

Then we will use visual editor (vi) to edit the file. Type:

Next we need to finish editing the Jupyter Configuration file we created

 $c = get_config()$ # Notebook config this is where you saved your pem cert c.NotebookApp.certfile = u'/home/ubuntu/certs/mycert.pem'

Check that it worked with:

(Optional: You can install specific versions of Scala with the following, just

\$ wget http://www.scala-lang.org/files/archive/scala-2.11.8.deb

instead of Ubuntu's default. In the console we will export the path for pip: \$ export PATH=\$PATH:\$HOME/anaconda3/bin

We need to install the python library py4j, in order to this we need to make

sure that pip install is connected to our Anaconda installation of Python

复制粘贴的时候会出现多余的空格 记得删除 \$ wget http://archive.apache.org/dist/spark/spark-2.0.0/spark-2.0.0-\$ sudo tar -zxvf spark-2.0.0-bin-hadoop2.7.tgz

每一次重新连接回EC2,需要重新告诉一下电脑,spark在哪
